# Graph factorization

Motivation

Known results

Another ideas

"Can an input graph  $H$  be represented as an edge disjoint union of subgraphs  $G_1, G_2, \dots, G_k$ , all of which are isomorphic to  $G$ ?"

# Petersen graph

Motivation

Known results

Another ideas

(a) Petersen graph

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 1 & 1 & 0 & 0 \end{bmatrix}$$

(b) Its adjacency matrix

**Question:** Can be the complete graph on 10 vertices decomposed into 3 copies of the Petersen graph?

Motivation

Known results

Another ideas

$$\det(\mathbf{A} - \lambda \mathbf{I}) = (\lambda - 3)(\lambda - 1)^5(\lambda + 2)^4$$

- 1 The corresponding eigenvector to the largest eigenvalue  $\lambda_{max} = 3$  is the constant vector  $\mathbf{v} = (1, 1, \dots, 1)$  (further referred as  $\mathbf{1}$ ).
- 2 We are looking for the decomposition of complete graph on 10 vertices decomposed into 3 copies of the Petersen graph.

$$\mathbf{A} = \mathbf{J} - \mathbf{I} = \mathbf{A}_1 + \mathbf{A}_2 + \mathbf{A}_3$$

where  $\mathbf{A}$  denotes the adjacency matrix of complete graph and  $\mathbf{A}_i = \mathbf{PAP}^T = \mathbf{PAP}^{-1}$ .

- 3 Also,  $\mathbf{A}_i$  is a symmetric matrix and hence the dimension of an eigenspace of eigenvalue  $\lambda$  (*geometric multiplicity*) is the multiplicity of  $\lambda$  as a root in the characteristic equation for  $\mathbf{A}_i$  (*algebraic multiplicity*).
- 4 Remark, that  $\det(\mathbf{A} - \lambda \mathbf{I}) = (\lambda - 9)(\lambda + 1)^9$  and  $\mathbf{1}$  is corresponding eigenvector to the eigenvalue 9.

Motivation

Known results

Another ideas

$$\det(A - \lambda I) = (\lambda - 3)(\lambda - 1)^5(\lambda + 2)^4$$

- 5**  $\mathbf{1}$  is an eigenvector of eigenvalue  $\lambda_1 = 3$  of all three  $A_i$  and so each has a 5-dimensional eigenspace of eigenvalue  $\lambda_2 = 1$  orthogonal to  $\mathbf{1}$  and hence contained in  $(\text{span}(\mathbf{1}))^\perp$  which is a 9-dimensional space.
- 6** **Any two** 5-dimensional subspaces of a 9-dimensional space must have a non zero vector, say  $v$ , in their intersection. **Thus there is a vector  $v$  that is an eigenvector of eigenvalue  $\lambda_2 = 1$  for both  $A_1$  and  $A_2$  ( $A_1 \cdot v = A_2 \cdot v = 1 \cdot v$ ) and moreover  $v$  is orthogonal to  $\mathbf{1}$  ( $\mathbf{1} \cdot v = 0$ ).**

$$(J - I)v = Jv - v = 0 - v = -v,$$

$$J - I = A_1 + A_2 + A_3,$$

$$(J - I)v = (A_1 + A_2 + A_3)v = A_1v + A_2v + A_3v,$$

$$-v = 2v + A_3v,$$

$$A_3v = -3v.$$

This is a contradiction since  $-3$  is not an eigenvalue of  $A_3$ .

# Generalization

Motivation

Known results

Another ideas

Let us consider decomposition to two graphs (for simplification):

$$\mathbf{A} = \mathbf{A}_1 + \mathbf{A}_2, \quad \mathbf{A}_2 = \mathbf{P}\mathbf{A}_1\mathbf{P}^T.$$

What about spectral decomposition?

$$\begin{aligned} \mathbf{V}^T \mathbf{D}_A \mathbf{V} &= \mathbf{U}_1^T \mathbf{D}_1 \mathbf{U}_1 + \mathbf{U}_2^T \mathbf{D}_2 \mathbf{U}_2, \\ \mathbf{V}^T \mathbf{D}_A \mathbf{V} &= \mathbf{U}_1^T \mathbf{D}_1 \mathbf{U}_1 + \mathbf{P}^T \mathbf{U}_1^T \mathbf{D}_1 \mathbf{U}_1 \mathbf{P}, \\ \mathbf{V}^T \mathbf{D}_A \mathbf{V} &= \mathbf{U}_1^T \mathbf{D}_1 \mathbf{U}_1 + (\mathbf{U}_1 \mathbf{P})^T \mathbf{D}_1 (\mathbf{P}^T \mathbf{U}_1^T)^T, \end{aligned}$$

$\mathbf{A}_1, \mathbf{A}_2$  have the same eigenvalues, but corresponding eigenvectors of  $\mathbf{A}_2$  are permuted ( $v_{A_2} = \mathbf{P} \cdot v_{A_1}$ ).

$$\mathbf{A}v = \mathbf{A}_1 v + \mathbf{P}\mathbf{A}_1\mathbf{P}^T v.$$

# Extension by Padraic Barlett (?)

Motivation

Known results

Another ideas

We might not know the precise eigenvalues - but rather just (say) their signs: one of them will have lots of negative small eigenvectors, while the other will just have one or two rather big negative ones ... [Lagrangian](#)

$$f_G(v) = \langle Av, v \rangle = \langle Av \rangle^T v = \sum_{(i,j) \in E(G)} v_i v_j.$$

## Proposition

Given a graph  $G$ , let  $W^+$  denote the space generated by all of the positive eigenvectors of  $A_G$ ,  $W^-$  the space generated by all of the negative eigenvectors, and  $W^0$  the eigenspace corresponding to 0. Notice that because  $A_G$  is symmetric, by the spectral theorem, we can write any element in  $\mathbb{R}^n$  as a sum of one element from each of these spaces. We claim that our function  $f_G$  is positive-semidefinite on the space  $W^+ \oplus W^0$  (i.e. the space generated by all of the nonnegative eigenvectors,) and negative-semidefinite on the space  $W^- \oplus W^0$ .

## Theorem

The complete graph  $K_n$  cannot be decomposed into less than  $n - 2$  complete bipartite graphs.

Motivation

Known results

## Lemma 8.5.1

Let  $X$  be a  $k$ -regular graph on  $n$  vertices with eigenvalues  $k, \theta_2, \dots, \theta_n$ . Then  $X$  and its complement  $\bar{X}$  have the same eigenvectors, and the eigenvalues of  $\bar{X}$  are  $n - k - 1, -1 - \theta_2, \dots, -1 - \theta_n$ .

Sketch of proof: (p.172)

$$A(\bar{X}) = J - I - A(X),$$

$$A(\bar{X})u_i = (J - I - A(X))u_i = (-1 - \theta_i)u_i, \quad u_i \perp \mathbf{1}.$$
